

CLINICIA PRIVACY AND SECURITY POLICIES

Nature of information stored in Clinicia

Clinicia is a cloud based software that allows doctors to store patient medical and treatment information and information about their clinics.

This information include

- Patient contact details
- Medical history of a patient,
- Details of the treatment done,
- Images and documents related to patient medical history and treatment
- Information about clinic location and doctors in that clinic
- Information related to clinic financials

All these information is accessible only to the doctor in whose account the information is created. The main doctor can further give permission to access this data to other doctors in his or her team and to the receptionists.

Clinicia stored data on Cloud

A cloud, in the case of Clinicia, is a server that is connected by internet. This server is a computer that is stored in a secured location called Data Center. Data Centers are large physical buildings where many such servers belonging to various organizations are kept. These buildings are highly secure from unauthorized physical access. The servers are continuously monitored by experts who keep them secure from unauthorized online attacks and data thefts.

Whenever a person uploads information in Clinicia, Clinicia stores this information in this server. This information can be retrieved from the same whenever required.

There are advantages of storing information in Cloud

1. Data Centers provide much stronger security and stability to the servers than an individual or a company can. More over these centers are manned by experts who have the capability to handle any physical or online threats.
2. Since the servers are connected through internet, data can be accessed from anywhere, anytime using any internet connected device.
3. The servers are high capacity servers that provide a good performance and which can be easily upgraded. This flexibility is highly limited when someone manages the servers on their own.

Storing data in cloud has some concerns to:

1. Data can be accessed only when you have access to internet.
2. Storing data in one location, can lead to concerns about unauthorized data privacy and data theft.
3. Data can be misused by the service provider.

To address these concerns and to ensure data privacy and security, Clinicia has established a set of policies.

Clinicia's policies on data privacy and security

Data privacy means ensuring that information which belongs to a particular person is kept private to that person only. This information is not shared with anyone unless permitted to do so by the owner himself or herself.

Data security is a process of keeping a data safe from loss or damage due to system failures or virus attacks and data theft due unauthorized access, hacking attempts or any such other attempts.

Clinicia's policy on data privacy

Clinicia allows doctors to access their own data only. It doesn't allow any doctor to access data stored by another doctor. Moreover, Clinicia does not use doctor's data for its benefit or to share with any third party.

In future, Clinicia might partners with third party providers for the benefit of the doctors. In such a situation, Doctors will have a clear option to either use those services or not. Clinicia will not share any information with the third party providers without the full consent of the doctors.

Data security in Clinicia

Clinicia uses state-of-the-art infrastructure to store data and to run Clinicia. The servers we use and other infrastructure needed are provided by Amazon Web Services (AWS). AWS servers are very secure and are used by many big corporations across the world. This infrastructure is also HIPPA certified.

AWS servers are kept in highly secure physical locations and are constantly monitored by experts for any unauthorized access and system failures.

Furthermore, Clinicia uses a secure (https) connection over which data is transferred between your device and the server.

Protecting data from thefts

Thefts happens from two locations. One is directly from the server, another is from a location where software developers access the servers. Generally these two are two completely different locations.

Since the servers are stored and maintained by Amazon Web Services, they already provide a very high level of security for physical and online access.

To control data theft at development level, Clinicia have a selective access policy for its developers. While software development is done on dummy environments, access to real live data is highly restrictive and is only accessed when a particular issue needs to be investigated.

Protecting data from system failures

When, due to some unforeseeable reason, a servers goes down or stops working, data can get corrupt and lost.

To handle such situations, Clinicia has back up policies in place using which data can be easily recovered. Moreover, AWS has built-in redundancies which enables restoring a server quickly thus providing uninterrupted service.
